I have used the atom matrix for this part and the **epsilon = A*S** matrix can be generated by running the ("**S_and_epsilon_generator.jl**") file.

▪ in julia console run `include("a,b S_and_epsilon_generator.jl")`

This will generate "atom_matrix.csv" and "epsilon.txt" files.

If the urea cycle reconstruction is elementally balanced, all components of the epsilon matrix should be zero, which is true in this case. (view "epsilon.txt")

Solution 1 (c)

The code for solving the FBA problem is given in “c run.jl”

- Upper bounds for the fluxes were calculated using:

$$v_{max,i} = k_{cat,i} \times E \times \prod_{i=1}^m \frac{C_i}{K_m + C_i}$$

- K_m values and metabolite concentration, C_i were obtained from Park et al Nat Chem Biol 12:482-9, 2016 and used to calculate:

For these values, the following order of preference was followed:

Homo sapiens > Mus musculus > other organism

Data for *S. cerevisiae* was used for the enzyme E.C.2.1.3.3

Note: I have assumed the metabolites involved in reaction v_5 can be exchanged through the boundary. Deactivate lines 25, 26 and activate lines 29 and 30 to see fluxes with **no boundary exchange of reaction v_5 metabolites** (in this case flux $v_5 = v_6 = 0.0$ mmol/gDW.hr to maximize urea)

- **in julia console run** `include("c run.jl")`

(answer) Optimum fluxes for maximum urea production
